### **Abstract**

It has been realized an animal telepathy experiment with rabbits. We studied couples of female rabbits (sisters) having the same mother isolated in pairs in their cage during 6 months. Then each rabbit is separated of its sister. One measures by plethysmography the blood flow variations of the two rabbits. They present frequent and spontaneous stresses, easily detectable by plethysmography. The stresses of the two sisters rabbits occur very often with an inferior gap of 5 seconds when these rabbits are temporarily removed. On the contrary, two rabbits who have never lived together in the same cage, have less often stresses occurring to less of 5 seconds of interval. Results are statistically very different with CHI-square ( $P < 0.0001$ ). This experiment seems to prove the telepathy existence. We continue our experiments thanks to the Bial Foundation.
